

All fired up

01/07/1999

?From time to time banks take a look at their power portfolio and shut their doors to merchant risk,? says Gerritt Ewing, director of project finance at Entergy in London, ?but they come back.? But why would banks turn away from UK power in the first place? Is this a case of an overheated market?

In this instance you have to know the history. In the past 10 years the UK power sector has been on a roller coaster journey. The break up of state monopolies and introduction of competition has paved the way for a succession of independent power projects. During that time competition for power concessions has hotted up as has the battle by lenders to win what are perceived as safe deals in a safe market.

In 1990 the UK electricity industry was divided into generation, transmission, supply and distribution. In the same year the UK's first independent power project, Lakeland, reached financial close followed shortly afterwards by Corby and Peterborough. These deals followed a US template established in the 1980s and so had a fixed-price turnkey construction contract, operation and maintenance contracts, long-term gas supply agreements and long-term contract for differences (CFDs).

By 1994 the situation changed again with power offtakers unwilling to bare the full CFD by themselves and demanding that sponsors should accept up to 75% of that risk. Humber power project was the first where equity providers, rather than the regional electricity companies, agreed to take a long-term view of electricity prices. This type of deal was quickly followed by First Hydro, the first independent power project to be financed in the capital markets. While the Rocksavage and Humber projects introduced gas tolling arrangements whereby the gas toller pays the project company a capacity payment to have the plant available for generation. If electricity prices are higher than gas prices there is an incentive for the plant to operate. If the electricity prices are lower than the toller's gas prices the station will not be used unless the operator enters into a separate agreement to purchase gas at spot prices.

And it is this absence of long-term contracts, where sponsors either purchase gas in the spot grid or sell power into the spot grid, which defines ?merchant risk'. Deals such as Enron's Sutton Bridge ? financed in the capital markets with a sterling eurobond and a Rule 144A bond ? AES Barry and Entergy's SaltEnd plant, led the way for UK merchant power deals.

With the exception of First Hydro and Sutton Bridge, all of the UK independent power projects financed since 1990 have been financed by banks. And while there are plans to refinance Entergy's Dam Head Creek deal in the capital markets, sponsors have generally tended to favour bank deals in the UK ? contrast this with the level of bond financings in the US power market. The high level of liquidity in the bank market and the high execution risk of issuing a bond coupled with poor market conditions have acted as a deterrent for sponsors tapping the UK capital markets for their power projects.

Bank financing is the order of the day. And as these deals have progressed the financing has become increasingly aggressive. The 1997 AES Barry transaction, in particular, was viewed by market observers when it signed as being very tightly priced. Viewed now Barry seems reasonable. Subsequent deals ? and there has been a glutt of them in the past six

months ? have been hotly contested. But there are some dangers.

With several deals in the syndication market at the same time, the feeling is that one deal will loose out in syndication and that appetite for such transactions will wane. Recent deals include Dam Head Creek and Coryton and still to close syndication, are Great Yarmouth, Shoreham, Barry refinancing and Fifoot.

Says Entergy's Ewing: ?The market for merchant risk has tightened up considerably. Now banks are pulling a shade down on their merchant lending business and seeing how the ones they have financed will do after construction.?

Have we gone too far?

But if some fear syndication risk based on an overcapacity of deals in the market, others believe that there has not been enough analysis of the risks involved in merchant deals. Michael Wilkins, director in the infrastructure finance department at rating agency Standard & Poor's in London casts doubt on the methodology used for recent merchant deals. Says Wilkins: ?There have been a lot of merchant deals in the market recently and most of them have been done in the bank market on very aggressive terms which is very surprising given the level of risk. There seems to be a low level of protection on a number of these deals.?

Wilkins outlines a series of risks, which he believes have not been worked sufficiently into recent deals. Says Wilkins: ? The problem is that the bank market has been very liquid for this kind of asset in recent months. But there are a lot of extra risks. There is considerable uncertainty over where the pool prices will go and consequently where merchant receipts will go. A lot of merchant power plants are heavily exposed to these dangers. They are relying on efficiencies in technology and the low cost of fuel. But technology improves very quickly and so their relative position in the pool can also change substantially.? But Wilkins points to a more fundamental problem ? the cost of fuel and the price paid for power.

The gas moratorium and new trading arrangements ? the next twists in the tale

But a highly competitive bank market is only part of the story. Uncertainty from the UK government has also cast doubt over the future of UK gas-fired independent power plants. Faced with a backlash from the UK coal industry at the end of 1997, the UK government imposed a moratorium on the granting of section 36 approval for new gas fired power plants. While there have been a trickle of deals which have managed to leapfrog this moratorium ? most controversially the 500MW Baglan Bay project near Port Talbot in Wales ? project sponsors and lenders are sceptical about when, if ever, the government will lift the moratorium. Part of reason why banks have been keen to grab the power deals in the past few months is because they are unsure when the next ones will come to market and, with several deals awarded to relationship banks without open bidding contests, competition has been ever tougher. With fewer transactions around it could be argued that banks will be even keener to win arranging mandates.

But tied in with the moratorium are changes in the electricity trading arrangements. In the past few months it has become clear that, in certain cases, sponsors and lenders are unaware of the implications new arrangements could have on their power plants.

Says Mark Coker, partner at law firm Freshfields in London: ?The trading review has been on the cards for a couple of years and it is a response to the perception that the pool price mechanism ? in operation since 1990 ? is too generator-friendly. The idea is that the government needs to change the rules on how electricity is to be traded to remove those imbalances.? Under the new arrangements, power purchasers would have a greater control in deciding what they should pay. In turn, power producers will have less say.

At a recent seminar in Washington, Callum McCarthy, the UK's new gas and electricity regulator, said that independent power producers and other generators cannot expect any specific provisions to be made as part of the reform process to guarantee that the commercial effect of their contracts is preserved. According to a May 1999 article by Freshfields: ?The universal pool will no longer exist. The new forward and future markets will place greater emphasis on bilateral trading. We therefore suggest that industry participants should consider the implications of this for the design of the contracts they will be using in the future.? The article adds: ?We expect to see significant changes in the way companies choose to sell power and the risks they accept.?

And while the decision on the moratorium and the new trading arrangements is imminent, banks and sponsors are looking elsewhere for their deals. This is not satisfactory. Says Neil Smith, managing director for InterGen UK in Edinburgh: ?We've supported pool reform but the government needs to deliver on the second half of the program which is to lift the moratorium in 2000. To do one without the other would send out the wrong signals.?

With the details of some transactions still to emerge, there is evidence that some lenders are picking their deals carefully. Says Stephen Crane, head of power structured finance at Greenwich NatWest in London: ?In Shoreham we were attracted by the gas contracts. Rather than having a single contract, there is a blend of contracts with different indexations ? three contracts with different maturities. The element of spot gas purchasing gets greater as time goes on. This gives the deal greater flexibility.? He adds that ?The UK power deals financed recently have been quite nicely tailored to sponsors. They are still attractive and with gas prices reasonably low and the turbine market competitive, they are strong deals.?

To be fair some lenders are heeding advice over future market uncertainties. Says Dick Burge, director of project finance at Bank of Scotland in Edinburgh: ?Yes deals have got progressively more aggressive ? it's obvious as markets learn to understand merchant risk and structures have become more flexible. Coverage ratios in particular are very important and you have to put your deal through some fairly severe downside scenarios.? In recent deals this has resulted in an increasing use of subordinated debt.

Says Coker: ?Recent deals have had debt-to-equity ratios of 60:40 rather than 80:20 or 90:10 and there have been higher levels of subordinated debt to give a cushion to the senior debt.?

In other cases sponsors are turning away from more conventional project finance-type deals. Financing for Ferry Bridge and Drax involve more acquisition-type financing, while Enron's innovative derivatives financing for its Teesside power plant could provide the template for other existing operators. Under the terms of this deal, debt securities secured on dividend payments to Enron Europe Power 3 are issued. Proceeds of these notes will be lent to Enron Europe to repay part of its existing bridge facility for its Teesside plant.

While some arrangers in non-recourse finance deals such as the AES Barry refinancing are aware of the potential risks, banks participating in syndication have been less enthusiastic. While the Barry refinancing deal was termed a ? connoisseurs deal?, it received a lukewarm response in syndication, indicating one of two things ? either it was badly structured, which it wasn't, or participant banks do not really understand merchant risk.

Says one banker: ?Over half the merchant power deals, in our view, do not have adequate structures. And many bankers are looking at the deals from a traditional IPP perspective. They are entirely inappropriate. A lot of banks just don't get it.?

Contract for differences

Contract for differences (CFD) arose as a result of the electricity trading arrangements in England and Wales (the Pool system). The pool itself is a financial settlement system between buyers and sellers of electricity. Physical delivery to end users is administered by the National Grid. CFDs acted as a purely financial instrument to fix the price of electricity in the same way as US-style power-purchase agreements.

UK IPP pricing and structures ? how the market is developing

Philip Carter reports.

The UK independent power project market has seen a renewed bout of activity over the past six months or so with a raft of deals being brought to market. But it is difficult, and perhaps too early, to spot any specific trends. ?I think the market is at a transitional stage at the moment,? says one power financier in London. ?And as such the picture is somewhat confused. However, I expect that the fate of the latest deals will give everyone a better idea of where the sector is going.?

Part of the reason for this uncertainty in direction is that merchant power projects still represent a relatively new asset class for syndicate banks, as such banks are cautious in committing to them.

These projects are essentially being banked on forecast cashflows from a still evolving system ? the English and Welsh power pool ? gaining credit approval is often a tough slog according to some bankers.

Structurally, the deals which have been, and are due to be sold are broadly similar in terms of multi-tranched facilities which are highly leveraged. These deals also typically feature a plethora of small tranches devoted to fuel costs, cost over-runs and working capital requirements. Another common feature is the growing use of full recourse equity bridge facilities. With many of the sponsors of these UK independent power projects operating and developing various other similar projects around the world, there are constraints on their limited equity. Sponsors are keen to take advantage of equity bridges during the construction phase rather than tying up equity which will remain essentially redundant until completion.

One area where there does seem to be a trend developing is in tenor. The first two of the new deals to come to market ? the £499.5 million (\$800 million) Dam Head Creek project sponsored by Entergy and the £476 million InterGensponsored Coryton plant ? have 17 and 19-year maximum maturities on their project debt elements respectively. Later deals have pushed out maturities a little further.

The £200 million project financing for the Shoreham plant, has a maximum maturity of 20 years. Moving out even further is the £250 million, 400MW Great Yarmouth project whose senior debt will have a 20.5 year maturity.

Other merchant power projects, which are not directly comparable, feature aggressive tenors also. The £123.75 million financing for the AES sponsored Fifoots Point ? the first test of the market's appetite for coal-fired merchant risk ? has a 19 year maximum maturity.

However, apart from Dam Head Creek and Coryton these deals have yet to be fully sold down successfully at time of press. And much of their respective fates will lie in how the market reacts to their pricing. Given the immaturity of the sector as an asset class and the long tenors involved, these deals have to be priced to clear but equally, banks have to compete aggressively to win these arranging mandates. As such they face a difficult balancing act between the sponsors' demands for the most cost-effective debt and the market's demand for appropriately priced risk.

Both Dam Head Creek and Coryton were closely matched on margins of a 125 basis points over Libor and 120bp respectively pre-completion. Post completion Dam Head Creek's drops to 115bp before reaching a final high of 145bp while Coryton steps up to 130bp on completion and then ratchets up to a final 160bp. Both deals were well supported in the market.

Deals still to be fully syndicated include Shoreham, Fifoots Point and Great Yarmouth (see pages 22 and 43). While these deals are considerably smaller in size than both Dam Head Creek and Coryton it remains to be seen whether their arrangers have struck the correct balance between aggression for their clients and market clearing pricing. Timing may be the crucial factor ? as each of these deals gets booked, bank capacity for similar new assets will begin to get harder and harder to locate.
